Condition Overview

Melanoma is a malignant tumor that originates from melanocytes, the pigment-producing cells in the skin. It is the most aggressive form of skin cancer and can spread rapidly to other organs if not detected and treated early. Key characteristics include:

| Feature | Typical Presentation |

|-----|-----|

| Appearance | Irregularly shaped, asymmetrical, or rapidly changing spots; colors may include black, brown, red, blue, or white |

| Growth | Can grow in size, depth, or change in color over weeks or months |

| Location | Commonly on areas exposed to the sun (face, neck, arms, legs), but can appear anywhere on the skin |

| Risk Factors | Fair skin, history of sunburns, excessive sun exposure, tanning beds, family history, numerous moles or atypical nevi |

Important Precautions

- Seek Immediate Professional Evaluation
- Schedule an appointment with a dermatologist or oncologist as soon as possible.
- A biopsy or excisional sample is typically needed for definitive diagnosis.
- Do Not Delay
- Melanoma can spread quickly; early detection improves treatment outcomes and survival rates.
- Maintain a Skin Cancer Friendly Lifestyle

-
